Automating Post Exploitation with Metasploit

Ruby Primer

Automating Post Exploitation with Metasploit

Disclaimer

The author of this class is not responsible for the use of this information. The information provided here is for the use of security professionals to automate post exploitation tasks while performing authorized security assessments and tasks.

Not all API calls available will be covered during this class, only those that are considered to be the most useful based on the instructors experience. The Metasploit Framework is in constant evolution. This course covers the current version of the framework at the time of delivery.

Automating Post Exploitation with Metasploit

RUBY PRIMER

- Created in Japan in 1995 by Yukihiro "Matz" Matsumoto
- Interpreter language, not compiled into machine code
- Object Oriented; everything is an object in Ruby
- The majority of the Metasploit framework is based on Ruby

- It is whitespace independent
- Tends to read like English
- Ruby is not Ruby on Rails! RoR is a Framework based on Ruby.
- The current versions of ruby are 1.8.X and 1.9.X

- To run ruby you can run in it in command
 - •ruby -e 'puts hello world'
- You can run ruby in a file
- Ruby can be used inside the Interactive Ruby Interpreter (IRB)

```
$ irb
irb(main):001:0>
```

We will use IRB for most of the examples

 Our Ruby examples will be run inside the IRB shell provided within msfconsole since this is a ruby primer for metasploit

```
$ ./msfconsole -q
msf > irb
[*] Starting IRB shell...
```

Documentation

- To get documentation on Ruby core libraries and the language visit http://www.ruby-doc.org/
- For framework documentation http://
 www.metasploit.com/learn-more/how-do-i-use-it/documentation.jsp
- Google works also:) like "ruby string"
- Another method is using the ri command line tool

 There are several ways in the framework to show output >>> print "hello world"

```
>> print "hello world"
hello world=> nil

>> print_good "hello world"
[+] hello world
=> nil

>> print_status "hello world"
[*] hello world
=> nil

>> print_error "hello world"
[-] hello world
=> nil
```

• Never use puts to print output to the terminal

- Everything in Ruby is an object (Except Variables)
- Each object is an instance of an object
- To get the type of object you use the .class method
- To get a list of the methods that can be used on an object you can list them with .methods
- To get a representation of the object you can use .inspect

Object Types

Variables

- Variables are not Objects, they are references to objects
- Once defined they are treated like objects
- They need to be defined before we can use them
- When naming use all lower case with underscores between words
- Do not use mix case or dashes

Variable Scopes

- Global \$variable (Never use in scripts and modules)
- Class @@variable (Never use in scripts and modules)
- Instance @variable
- Local variable
- Block variable
- * Constants start with capital letters

Assignment Operators

Operator	Description
	Simple assignment operator, Assigns values from right side operands
=	to left side operand
	Add AND assignment operator, It adds right operand to the left
+=	operand and assign the result to left operand
	Subtract AND assignment operator, It subtracts right operand from
-=	the left operand and assign the result to left operand
	Multiply AND assignment operator, It multiplies right operand with
*=	the left operand and assign the result to left operand
	Divide AND assignment operator, It divides left operand with the right
/=	operand and assign the result to left operand
	Modulus AND assignment operator, It takes modulus using two
%=	operands and assign the result to left operand
	Exponent AND assignment operator, Performs exponential (power)
**=	calculation on operators and assign value to the left operand

Integers Numbers

- Integers are objects that represent positive numbers.
- There are 2 subclasses of integers Fixnum (machine word -1bit) and Bignum (Any larger number than a word)
- Integers can be positive or negative numbers
- You can get a string representation of a number as an integer with .to_i

Float Numbers

- Float is nothing more than decimal numbers & can be positive or negative
- Arithmetic of integer numbers will always return an integer number, if any element is a float then float is returned

```
>> 8/2
=> 4
>> 8/3
=> 2
>> 8/3.0
=> 2.66666666666666665
```

Float Rounding

 Converting a float object to an integer: the rounding varies on the method used

```
>> 2.45.to_i
=> 2
>> 2.55.to_i
=> 2
>> 2.55.round
=> 3
>> 2.45.round
=> 2
>> 2.45.ceil
=> 3
>> 2.45.floor
=> 2
```

Arithmetic Operators

Operator	Description
	Addition - Adds values on either side of the
+	operator
	Subtraction - Subtracts right hand operand from
-	left hand operand
	Multiplication - Multiplies values on either side of
*	the operator
	Division - Divides left hand operand by right hand
/	operand
	Modulus - Divides left hand operand by right
%	hand operand and returns remainder
	Exponent - Performs exponential (power)
**	calculation on operators

- Strings are a series of characters strung together
- Strings between quotes(") are evaluated
- Strings between single quotes(') are literal

```
>> "HKLM\System"
=> "HKLMSystem"
```

Strings-can be added together with the +
 "HKLM\\System" operator

```
>> "msf" + " " + "Rocks"
=> "msf Rocks"
```

 You can evaluate Ruby code inside a string with double quotes with #{}

```
>> name = "Carlos"
=> "Carlos"

>> "hello #{name}"
=> "hello Carlos"

>> " 1 + 2 = #{1+2}"
=> " 1 + 2 = 3"
```

You can also append to a string

```
>>> todo_list = "1. Buy groceries\n"
=> "1. Buy groceries\n"
>>> todo_list << "2. Take car to get serviced\n"
=> "1. Buy groceries\n2. Take car to get serviced\n"
```

Escape Sequence	Description
\a	Bell or alert
\b	Backspace
\cx	Control-x
\C-x	Control-x
\e	Escape
\n	Newline
\r	Carriage return
\s	Space
\t	Tab
\v	Vertical tab
\x	Special Character x like backslash or quotes
\xnn	Hexadecimal notation, where n is in the range 0.9, a.f, or A.F

Some helpful methods are split, chomp and strip

```
>> todo_list.split("\n")
=> ["1. Buy groceries", "2. Take car to get serviced"]
>> "file.txt \n".chomp
=> "file.txt "
>> " file.txt "
=> "file.txt"
```

Array

- Arrays are an ordered, integer indexed collection of objects.
- Arrays can have a mix of different objects types as its elements (Numbers, Strings, Arrays ..etc)
- Each element of an array can be called by the integer index value that represent its position; the index starts at 0

Array

Requesting specific element of an array

```
>> sampl_array = ["1",2,3.4,nil]
=> ["1", 2, 3.4, nil]
>> sampl_array[3]
=> nil
>> sampl_array[2]
=> 3.4
```

Adding and Removing from an Array

```
>> array1 = [1,2,3,4,5]
=> [1, 2, 3, 4, 5]
>> array2 = ["a", "b", "c"]
=> ["a", "b", "c"]
>> array3 = array1 + array2
=> [1, 2, 3, 4, 5, "a", "b", "c"]
>> array3 - ["a", "b"]
=> [1, 2, 3, 4, 5, "c"]
>> array2 << "d"
=> ["a", "b", "c", "d"]
```

Array

Checking if an element in an Array is present

```
>>> array2 = ["a", "b", "c", "d"]
=> ["a", "b", "c", "d"]
>>> array2.include?("f")
=> false
>>> array2.include?("a")
```

• Removing duplicates in an array

```
>> array1 = ["a","b","b",3,3,3,4,5,6,7]
=> ["a", "b", "b", 3, 3, 3, 4, 5, 6, 7]
>> array1.uniq
=> ["a", "b", 3, 4, 5, 6, 7]
```

Hashes

- Hashes are an unordered, object indexed (key) collection of objects (value), known as dictionaries in other languages
- Creating a hash, looking by key and adding an element

```
>> hash1 = { 'path' => "c:\\boot.ini", 'file' => "boot.ini"}
=> {"path"=>"c:\\boot.ini", "file"=>"boot.ini"}
>> hash1['path']
=> "c:\\boot.ini"
>> hash1['description'] = "Windows boot parameter file"
=> "Windows boot parameter file"
>> hash1
=> {"path"=>"c:\\boot.ini", "file"=>"boot.ini", "description"=>"Windows boot parameter file"}
```

Hashes

Check if it contains a value

```
>> hash1.value?('boot.ini')
=> true
>> hash1.value?('autoexec.ini')
=> false
```

Merging together 2 hashes

```
>>> hash1 = { "key1" => 1, "key2" => 2}
=> { "key1" => 1, "key2" => 2}
>>> hash2 = { "key3" => 3, "key4" => 4}
=> { "key3" => 3, "key4" => 4}
>>> hash1.merge(hash2)
=> { "key1" => 1, "key2" => 2, "key3" => 3, "key4" => 4}
```

Symbols

- Symbols are labels to identify a piece of data
- A symbol will only be stored in memory one time

```
>> :labe1.object_id
=> 489128

>> :labe1.object_id
=> 489128

>> "label1".object_id
=> 70185273123240
```

• They are used mostly for Hash keys

```
=> 70185273114580
```

```
>> hash3 = { :file => "secretdata.doc", :path => "c:\\secret\\"}
=> {:file=>"secretdata.doc", :path=>"c:\\secret\\"}
```

Symbols

 Note: In Ruby 1.9.x you can use also as a symbol name: format, this will break support of 1.8.x
 Ruby in your modules and plugins.

Booleans

- They are either true or false
- They are used for control structures
- True and False are objects
 - >> true.class
 - => TrueClass
 - >> false.class
 - => FalseClass

Comparison Operators

Operator	Description
	Checks if the value of two operands are equal or not, if yes then
==	condition becomes true.
	Checks if the value of two operands are equal or not, if values are not
!=	equal then condition becomes true.
	Checks if the value of left operand is greater than the value of right
>	operand, if yes then condition becomes true.
	Checks if the value of left operand is less than the value of right
<	operand, if yes then condition becomes true.
	Checks if the value of left operand is greater than or equal to the
>=	value of right operand, if yes then condition becomes true.
	Checks if the value of left operand is less than or equal to the value of
<=	right operand, if yes then condition becomes true.
	Combined comparison operator. Returns 0 if first operand equals
	second, 1 if first operand is greater than the second and -1 if first
<=>	operand is less than the second.
===	Used to test equality within a when clause of a case statement.
	True if the receiver and argument have both the same type and equal
.eql?	values.
equal?	True if the receiver and argument have the same object id.

Booleans

Using comparison Operators

```
>> 1 == "1"
=> false

>> 1 == "1".to_i
=> true

>> 1 > 2
=> false
```

Logical Operators

Operator	Description
	Called Logical AND operator. If both the operands are true then then
and	condition becomes true.
	Called Logical OR Operator. If any of the two operands are non zero
or	then then condition becomes true.
	Called Logical AND operator. If both the operands are non zero then
&&	then condition becomes true.
	Called Logical OR Operator. If any of the two operands are non zero
	then then condition becomes true.
	Called Logical NOT Operator. Use to reverses the logical state of its
	operand. If a condition is true then Logical NOT operator will make
!	false.
	Called Logical NOT Operator. Use to reverses the logical state of its
	operand. If a condition is true then Logical NOT operator will make
not	false.

Booleans

Logical Operators

```
>> 1 > 2 && 1 == 1
=> false

>> 1 > 2 || 1 == 1
=> true

>> 1 > 2 or 1 == 1
=> true

>> 1 > 2 and 1 == 1
=> false
```

Ranges

- Short notation object for a range of characters or numbers
- There are 2 types of ranges: inclusive and exclusive, the exclusive excludes the last value

```
>> r = 1..10
=> 1..10

>> [*r]
=> [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

>> r = "a".."f"
=> "a".."f"

>> [*r]
=> ["a", "b", "c", "d", "e", "f"]
```

Control Structures

If Conditional

 The If statement will execute a block of code & if the condition is true, returns a true object

```
x, y = 1, 2
# Execute if condition is true
if x > y
    puts "x is more than y ... WTF!"
end
# if condition is not true execute one action, if not execute alternate action
if x > y
    puts "x is more than y ... WTF!"
else
    puts "y us more than x"
end
# if we want to check more than one condition
if condition
    action
elsif condition
    action
end
```

If Conditional

• The "if" conditional can be used as a modifier

```
print_status("Verbose mode is enabled") if datastore['VERBOSE']
```

Nil object is treated as false

```
>> nil_value = nil
=> nil

>> puts "variable is empty" if not nil_value
variable is empty
=> nil

# Recommended method
>> puts "variably is empty" if nil_value.nil?
variably is empty
=> nil
```

For empty variables use .empty?

Unless Conditional

Works just like if but the condition is inverted

```
>> target_compat = false
=> false
>> print_error("Target is not compatible") unless target_compat
[-] Target is not compatible
=> nil
```

 It can use else just like if and you can mix it with elsif - NOT Recommended for readability

Case Conditional

Used when multiple conditionals are needed.
 Recommended when more than 2 multiple conditionals are needed.

```
case name
  when "Path"
    print_status "\tPath: #{val}"
    path = val
  when "Type"
    print_status "\tType: #{val}"
    stype = share_type(val.to_i)
  when "Remark"
    remark = val
end
```

Regular Expressions can be used for the condition

Loops

 They are used to run a piece of code over and over until it is told to stop

```
x = 0
loop do
    x = x + 1
    print_status("x is #{x}")
    break if x == 100
end
```

You control the loop with Control Calls

Control Call	Description
break	Terminate the whole loop
next	Jump to the next loop
redo	Restart the loop
retry	Start the whole loop over

Boolean Loops

- Are loops that execute while a boolean conditional is met
- While Boolean Loop

Boolean Loops

Until Boolean Loop

```
>> X = 0
=> 0
>> until x > 5
>> print_status("x is #{x}")
>> x = x + 1
>> end
[*] x is 0
[*] x is 1
[*] x is 2
[*] x is 3
[*] x is 4
[*] x is 5
=> nil
```

- Are like loops; they traverse a set of data
- There are 2 iterators for Integers and floats named upto() and downto()

```
>> 1.upto(6) do lil
?>     print_status(i)
>>     end
[*] 1
[*] 2
[*] 3
[*] 4
[*] 5
[*] 6
=> 1
```

```
>> 6.downto(0) do lil
?>          print_status(i)
>>          end
[*] 6
[*] 5
[*] 4
[*] 3
[*] 2
[*] 1
[*] 0
=> 6
```

 For range the iterators available are range.each and range.step(n)

For can be used as an iterator like in other languages

```
>> for n in (1..6)
>> print n.to_s + " "
>> end
1 2 3 4 5 6 => 1..6
```

 For strings the iterators available are str.each_line, str.each_char and str.each byte

```
>> multi_line_str = "line1\nline2\nline3\n"
=> "line1\nline2\nline3\n"
>> multi_line_str.each_line do III
?>         print_status(l.strip)
>>         end
[*] line1
[*] line2
[*] line3
=> "line1\nline2\nline3\n"
```

 The for iterator can be used, behaves like each_line

 For Array the iterators available are arr.each, arr.each_index and arr.each with index

```
\Rightarrow arr = [1,2,3,4,5,6]
\Rightarrow [1, 2, 3, 4, 5, 6]
                                         >> arr.each_with_index do li,dl
                                                 print_status("value:#{i} index:#{d}")
>> arr.each do lil
       print_status(i)
                                         >> end
                                         [*] value:1 index:0
>> end
[*] 1
                                         [*] value:2 index:1
                                          [*] value:3 index:2
                                         [*] value:4 index:3
[*] 4
                                         [*] value:5 index:4
                                         [*] value:6 index:5
                                         \Rightarrow [1, 2, 3, 4, 5, 6]
[*] 6
\Rightarrow [1, 2, 3, 4, 5, 6]
```

• The for iterator can be used, behaves like each

 For Hash the iterators available are hsh.each, hsh.each_key, hsh.each_value and hsh.each_pair

```
>> hsh = {:company => "Rapid7", :name => "HD", :project => "Metasploit"}
=> {:company=>"Rapid7", :name=>"HD", :project=>"Metasploit"}
>> hsh.each_pair do |k,v|
?> print_status("#{k} = #{v}")
>> end
[*] company = Rapid7
[*] name = HD
[*] project = Metasploit
=> {:company=>"Rapid7", :name=>"HD", :project=>"Metasploit"}
```

• The for iterator can be used, behaves like each

- Methods are also known as functions in other scripting and programing languages
- They tend to be blocks of code that serve a specific function
- Variables declared inside methods are local to the methods
- The last assignment in a method becomes the default return value for the method, do not rely on this

 Methods are defined with the keyword of def and the block of code is closed with the keyword of end

```
def get_base_info
    sys_data = session.sys.config.sysinfo
    sys_data['User'] = session.sys.config.getuid
    sys_data['PID'] = session.sys.process.getpid
    sys_data["PWD"] = session.fs.dir.getwd
    return sys_data
end
```

 It is recommended that you use return to specify the data given back by a method instead of relying on the last assignment behavior

 You can pass values to methods thru a list of comma separated variables known as arguments

```
• def eventlog_clear(evt = nil)
    evntlog = []
    if evt.nil?
        evntlog = eventloglist
    else
        evntlog << evt
    end
    evntlog.each do lel
        log = session.sys.eventlog.open(e)
        log.clear
    end
    return evntlog
end</pre>
```

 You can set default values to arguments by declaring them in the method definition

- The number of arguments and order are of importance; they should be specified in the same order as they are declared
- Place default variables at the end of the list to make calling methods simpler
- If the argument is optional place it at the end with a value of nil or an empty variable ("",[],{})
- A return statement will also exit a method

Instance variables (Variables that start with "@")
can be used to have an object that all methods
inside the class or script can access.

Questions?

Automating Post Exploitation with Metasploit
